NEW Early Alzheimer's Research Study

Frequent forgetfulness and difficulty with routine tasks may be more than just aging.

It's important to identify symptoms early. The Aware Study is evaluating an investigational medication targeting tau protein to see if it may slow the progression of Alzheimer's disease.

Qualified participants must:

- Be 55–85 years old
- Have symptoms of mild cognitive impairment or mild Alzheimer's disease
- Have a study partner who is willing to participate in the study and attend some study visits

Qualified participants:

- Will receive all study-related care and medication at no cost
- Will be monitored by doctors who are experienced in Alzheimer's disease
- May potentially help future Alzheimer's research and treatment
